Ex. 1

Write down Newton's formula for finding the minimum of $f(x) = (3x^4 - 4x^3)/12$ in the range [-10, 10]. Then, implement it in R.

Solution:

```
\begin{split} f(x) &= (3x^4 - 4x^3)/12 \\ f'(x) &= \frac{12x^3 - 12x^2}{12} = x^3 - x^2 \\ f''(x) &= 3x^2 - 2x \end{split}
```

Using Newton's formula

fetch_values(3)

```

It looks like the minimum is at 1 since given multiple starting values, it converges to 1.

Ex. 2

Explore optimize() in R and try to solve the previous problem.

Solution:

```
f <- function(x) {
    (3*x^4 - 4*x^3)/12
}

x_min <- optimize(f, c(-10, 10))
x_min

## $minimum
## [1] 0.9999986</pre>
```

\$objective ## [1] -0.08333333

Here we can confirm that minimum is at 1 and value of given function is -0.0833.

Ex. 3

Use any optimization algorithm to find the minimum of $f(x,y)=(x-1)^2+100(y-x^2)^2$ in the domain $-10 \le x, y \le 10$. Discuss any issues concerning the optimization process.

Solution:

We will use Newton's method for optimization of multivariate function.

The equation is

$$x_{t+1} = x_t - H^{-1} \nabla f(x, y)$$

where ∇f is the gradient vector and H is Hessian matrix

Starting value.

$$\begin{split} x_0 &= \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \nabla f(x,y) &= \begin{bmatrix} (x-1)^2 \\ 100(y-x^2)^2 \end{bmatrix} \end{split}$$

We will start by finding Hessian matrix.

$$\begin{split} f_{xx} &= 1200x^2 + 2 - 400y \\ f_{xy} &= -400x \\ f_{yy} &= 200 \\ f_{yx} &= -400x \end{split}$$

$$\begin{split} H &= \bigtriangledown^2 f(x,y) = \begin{bmatrix} 2 & -0 \\ -0 & 200 \end{bmatrix} \\ H^{-1} &= \begin{bmatrix} 0.5 & 0 \\ 0 & 0.005 \end{bmatrix} \\ \text{With } \mathbf{t} &= 0 \ x_1 = x_0 - H^{-1} \bigtriangledown f(x,y) \\ x_1 &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} - \begin{bmatrix} 0.5 & 0 \\ 0 & 0.005 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\ x_1 &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} - \begin{bmatrix} 0.5 \\ 0 \end{bmatrix} \\ x_1 &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} - \begin{bmatrix} 0.5 \\ 0 \end{bmatrix} \end{split}$$

Given this, we can say f(x,y) will converge into a single point as we go through further values of t.

Ex. 4

Explore the optimr package for R and try to solve the previous problem.

Solution:

```
f xy <- function(param) {</pre>
  (param[1] - 1)^2 + 100 * (param[2] - param[1]^2)^2
}
options(scipen = 999)
optimr(c(-10,10), f_xy, method = "L-BFGS-B")
## $par
